Note: Within nine months from the publication of the mention of the grant of the European patent, any person may give notice to the European Patent Office of opposition to the European patent granted. Notice of opposition shall be filed in a written reasoned statement. It shall not be deemed to have been filed until the opposition fee has been paid. (Art. 99(1) European patent convention).

Courier Press, Leamington Spa, England.

Description

The present invention relates to fragments of specific deoxyribonucleotide sequences that promote the secretion of gene products from cells and in particular to recombinant DNA transfer vectors that contain these fragments.

Recent developments in biochemistry have led to the construction of recombinant DNA transfer vectors in which, transfer vectors, for example plasmids, are made to contain exogenous DNA. In some cases the recombinant incorporates heterologous DNA that codes for polypeptides that are ordinarily not produced by the organism susceptible to transformation by the recombinant vehicle.

In its basic outline a method of endowing a microorganism with the ability to synthesise a new protein involves three general steps:

(a) isolation and purification of the specific gene or nucleotide sequences containing the genetically coded information for the amino acid sequence of the desired protein or polypeptide,

(b) recombination of the isolated gene or nucleotide sequence with an appropriate transfer vector, typically DNA of a bacteriophage or plasmid to form a recombinant transfer vector that codes, in part, for the production of the desired protein or polypeptide,

(c) transfer of the vector to the appropriate microorganism and selection of a strain of the recipient microorganism containing the desired genetic information.

Provided the gene or nucleotide sequence expresses its protein or polypeptide in the chosen microorganism, growth of the microorganism should then produce the desired protein or polypeptide in significant quantities.

Once the microorganism has been cultured, the protein or polypeptide must be isolated from the undesired materials. This step is considerably facilitated if the majority of the desired protein or polypeptide is present in the culture medium and/or the periplasmic space of the microorganism. In other words purification may be performed in a more efficient manner if, once expressed, the protein or polypeptide passes through the cell membrane and out of the cytoplasm.

The passage of the protein or polypeptide through the cell membrane is desirable for two main reasons. First the desired protein or polypeptide will generally be foreign to the microorganism in which it is expressed. In many cases, therefore, it will be quickly broken down by proteolytic enzymes etc. in the cell's cytoplasm and will, subsequently, have a short half life within the cell. By transferring the protein or polypeptide out of the cytoplasm soon after expression the stability of the protein or polypeptide will be greatly increased. Second the number of unwanted genetic materials and products (from which the desired protein or polypeptide must be isolated) will be far greater in the cell's cytoplasm than in the culture medium and/or in the cell's periplasmic space. It can be seen that on both of the above counts the transfer of the protein or polypeptide through the cell membrane and out of the cytoplasm will greatly facilitate protein or polypeptide isolation.

One way in which the secretion of gene products from the cell's cytoplasm may be promoted is to produce, within the cytoplasm, a preprotein or prepolyptide in which the desired protein or polypeptide is preceded by a signal polypeptide. The predominantly hydrophobic signal polypeptide directs the desired protein or polypeptide to the cell's periplasmic space, where the signal peptide is removed as the desired protein or polypeptide traverses the cell membrane.

Many of the known signal peptides contain cysteine residues. These residues have been found to react in the cell membrane and thereby inhibit the efficient transfer of the desired gene product out of the cell.

It is the primary object of the present invention to provide recombinant DNA transfer vectors containing a leader sequence polynucleotide that codes for a signal peptide that is cysteine free. Other objects and advantages of the present invention will become apparent from the following description thereof.

According to the present invention there is provided a recombinant DNA transfer vector comprising a leader sequence polynucleotide coding for signal polypeptide of formula I,

Met-Arg-Pro-Ser-Ile-His-Arg-Thr-Ala-Ile-Ala-Ala-Val-Leu-Ala-Thr-Ala-Phe-Val-Ala-Gly-Thr

The transfer vector may be a bacteriophage or, which is preferred, a plasmid. Preferably the majority of the codons in the nucleotide sequence are those preferred for the expression of microbial genomes. Suitable codons are listed in UK 1,568,047 and UK 2007675A, and these publications are therefore incorporated herein by reference.

In one preferred embodiment of the present transfer vector the nucleotide sequence has formula II

5'	ATG	CGC	CCA	TCC	ATC	CAC	CGC	ACA	
	GCC	ATC	GCC	GCC	GTG	CTG	GCC	ACC	
	GCC	TTC	GTG	GCG	GGC	ACC	— 3'		

The nucleotide sequence coding for the signal polypeptide (the leader sequence polynucleotide) will preferably be downstream of and in reading phase with a bacterial or a yeast promoter and a prokaryotic

ribosome binding site in the transfer vector. Moreover the leader sequence polynucleotide will either be upstream of an insertion site for a structural gene or, which is preferred, will be upstream of and in reading phase with a structural gene coding for a desired protein or polypeptide. Preferably the gene codes for a eukaryotic, particularly a mammalian, protein or polypeptide.

5 The structural gene may code for such prokaryotic proteins as *E. coli* β -galactosidase or *Pseudomonas* carboxy peptidase G_2 (CPG₂) (Carboxypeptidase G_2 is an enzyme, produced by *Pseudomonas* species strain RS-16, that has application in cancer chemotherapy. It is a Zn^{2+} containing dimer of $2 \times 42,000$ daltons and has high affinities (K_m values of 10^{-5} or $10^{-6}M$) for both 5-methyltetrahydrofolate, the predominant
10 circulatory form of folate in mammals and for the folic acid antagonist methotrexate (MTX), which is widely used in cancer chemotherapy. The enzyme may be used directly for the plasma depletion of reduced folates, essential as co-factors in purine and particularly in pyrimidine biosynthesis. CPG₂ has been shown to inhibit the development of the Walker 256 carcinoma *in vivo* and to remove MTX from circulation in patients where prolonged exposure to high doses of MTX leads to toxicity).

Examples of transfer vectors according to the present invention that code for CPG₂ are pNM1, pNM111,
15 pNM14, pNM21, pNM22, pNM31, pNM32 and pLEC3.

The promoter is preferably a high expression bacterial or yeast promoter for the structural gene in a variety of hosts. The particular choice of promoter will depend on the microorganism to be transformed. For example the transformation of *E. coli* will generally be effected by a transfer vector in which an *E. coli* promoter controls the expression of the structural gene. Examples of *E. coli* promoters are those present in
20 the plasmids pBR 322 and pAT 153. By contrast, the transformation of *Pseudomonas* species will generally be effected by a transfer vector in which a *Pseudomonas* promoter controls the expression of the structural gene. Examples of *Pseudomonas* promoters are those present in the plasmid pKT 230 or *Pseudomonas* chromosomal DNA.

In order to express the structural gene the present transfer vector will be transformed into a suitable
25 microorganism. According to a further aspect of the present invention there is provided a microorganism transformed by a recombinant DNA transfer vector according to this invention. The microorganism will preferably be a bacterium or yeast in which high expression of the structural gene, within the transfer vector, occurs. Depending on the choice of promoter the microorganism may be a strain chosen from one of the following bacteria *E. coli*, *Pseudomonas* or the yeast *Saccharomyces cerevisiae*.

30 Having transformed the microorganism, the protein or polypeptide, for which the structural gene codes, may then be expressed by culturing the transformed microorganism in a culture medium. It is the primary advantage of the present invention that culturing the transformed microorganism affords a preprotein or prepolyptide in which the desired protein or polypeptide is preceded by the present signal polypeptide. This means that soon after expression the signal polypeptide directs the desired protein or
35 polypeptide to the cell's periplasmic space, where the signal polypeptide is removed as the desired protein or polypeptide traverses the cell membrane. Since the present signal polypeptide is free of cysteine residues the desired gene product will be efficiently secreted through the membrane.

The present transfer vectors may be prepared by any of the methods that are well known in the recombinant DNA art. For example the leader sequence polynucleotide may be synthesised by the
40 modified triester method of K. Itakura et al, *JACS*, 1975, 97, 7327 or by the improved oligodeoxynucleotide preparation described in UK 2007675A. The disclosure of both of these references is incorporated herein by reference. The synthesised polynucleotide may then be inserted in a transfer vector, preferably a plasmid. In the transfer vector it will preferably be downstream of and in reading phase with a bacterial or a yeast promoter and a prokaryotic ribosome binding site. The leader sequence polynucleotide should also be
45 either upstream of a structural gene insertion site or upstream of and in reading phase with a structural gene.

Alternatively, DNA fragments containing the leader sequence polynucleotide may be obtained from natural sources, in particular from the chromosomal DNA of *Pseudomonas* species strain RS-16. In this particular case a polynucleotide (formula II above) coding for the present signal polypeptide immediately
50 precedes a structural gene coding for CPG₂. A number of the DNA fragments containing this leader sequence polynucleotide may therefore be recognised by their ability, on insertion into a plasmid and transformation of a microorganism by the resultant recombinant vector, to enable a microorganism to grow on folate. Examples of such recombinant transfer vectors that contain both a polynucleotide coding for the present signal polypeptide (formula II above) and a structural gene coding for CPG₂ are pNM1,
55 pNM111, pNM14, pNM21, pNM22, pNM31, pNM32 and pLEC3. Of course, once a Fol^+ recombinant vector has been obtained in this way it may be subcloned to afford alternative vectors (either Fol^+ or Fol^-) that also contain a polynucleotide coding for the present signal polypeptide.

Once a suitable DNA fragment has been isolated it may then be inserted in a transfer vector, preferably a plasmid. In the transfer vector the leader sequence polynucleotide on the inserted fragment should be
60 downstream of and in reading phase with a bacterial or a yeast promoter and a prokaryotic ribosome binding site. The leader sequence polynucleotide should also be either upstream of a structural gene insertion site or upstream of and in reading phase with a structural gene.

The structural gene for insertion downstream of and in reading phase with the present leader sequence polynucleotide may be obtained, for example, by the synthetic methods mentioned above (this is
65 particularly useful for the preparation of genes coding for small proteins). Alternatively the structural gene

may be prepared from m=RNA by the use of the enzyme reverse transcriptase or may be isolated from natural sources (chromosomal DNA).

An example of the latter method is the isolation of DNA fragments containing a polynucleotide sequence (shown in Table 1) coding for the enzyme CPG₂ (amino acid sequence also shown in Table 1) from *Pseudomonas* species strain RS-16 chromosomal DNA. Examples of plasmids containing a CPG₂ structural gene, as well as a polynucleotide coding for the present signal polypeptide (formula II above), are pNM1, pNM111, pNM14, pNM21, pNM22, pNM31, pNM32 and pLEC3.

Once prepared or isolated the leader sequence polynucleotide and the structural gene will be inserted into a transfer vector, preferably a plasmid, to form a recombinant DNA transfer vector according to the present invention. The insertion step or steps will preferably be effected by one of the well known techniques in this art that employ restriction endonucleases, see for example the methods discussed in UK 2090600A, the disclosure of which is incorporated herein by reference. The choice of transfer vector will be determined by the microorganism in which the leader sequence polynucleotide and structural gene are to be expressed. Generally the transfer vector will be a cloning vehicle that is suitable for transforming the chosen microorganisms and that displays a phenotypical characteristic, such as antibiotic resistance, by which the recombinant transfer vectors may be selected. Thus, if the microorganism is to be *E. coli*, then suitable transfer vectors will be the *E. coli* plasmids pBR322 and pAT153. Alternatively, if the microorganism is to be *Pseudomonas* then a suitable transfer vector will be *Pseudomonas* pKT230.

Amino acids 1 to 22 are the present signal polypeptide.

Amino acids 23 to 415 are the CPG₂ structural gene.

NB The leader sequence polynucleotide is the preferred polynucleotide of formula II.

20 The present recombinant DNA transfer vectors, microorganisms transformed by the present recombinant DNA transfer vectors and processes for the preparation of said vectors and microorganisms will now be described by way of example only, with particular reference to the Figures in which:

Figure 1 is a restriction enzyme cleavage site map of pNM1,

25 Figure 2 is a restriction enzyme cleavage site map of pNM111.

Figure 3 is a restriction enzyme cleavage site map of pNM14,

Figure 4 is a restriction enzyme cleavage site map of pNM21,

Figure 5 is a restriction enzyme cleavage site map of pNM22, and

Figure 6 illustrates the process for the preparation of a recombinant plasmid containing both the 30 present leader sequence polynucleotide and the β -Galactosidase structural gene, and

Figure 7 is a restriction enzyme cleavage site map of pLEC3.

Materials and methods

Bacterial strains and plasmids

35 The bacterial strains used were *Escherichia coli* W5445 (*pro leu thi thr⁺ sup E44 lac Y ton A r⁻ m⁻ Str^r*) *Pseudomonas putida* 2440 (*r⁻*) and *Pseudomonas* sp strain RS-16. The plasmids employed were pBR322 (F. Bolivar et al Gene, 1977, 2, 95), pAT153 (A. J. Twigg et al, Nature, 1980, 283, 216) and pKT230 (M. Bagdasar'In et al, Gene 1981, 16, 237) and pROG5 (R. F. Sherwood et al, The Molecular Biology of Yeast, 1979 Cold Spring Harbor Publications).

Media and culture conditions

40 *E. coli* was routinely cultured in L-broth (1% tryptone, 0.5% yeast extract, 0.5% NaCl). Solidified medium (L-agar) consisted of L-broth with the addition of 2% (w/v) agar (Bacto-Difco). Antibiotic concentrations used for the selection of transformants were 50 μ g/ml ampicillin, 15 μ g/ml tetracycline and 45 30 μ g/ml kanamycin. In the case of *E. coli* these were conducted in 2YT liquid medium (1.6% tryptone, 1% yeast extract, 0.5% NaCl) containing 1% glucose, and 0.05% folate where appropriate. The pseudomonads were grown in a minimal salts solution consisting of per litre: MgSO₄, 0.05 g; CaCl₂, 2H₂O, 0.05 g; FeSO₄ · 7H₂O, 0.005 g; MnSO₄, 0.0015 g; Na₂MbO₄, 2H₂O, 0.0015 g; KH₂PO₄, 5 g; K₂HPO₄ · 3H₂O, 12 g; glutamate, 10 g. The minimal medium employed for *E. coli* was M9 medium (J. Miller, Experiments in 50 molecular genetics, Cold Spring Harbor Laboratory, Cold Spring Harbor, New York, 1972).

Purification of DNA

Plasmids were purified from chloramphenicol amplified cultures (D. B. Clewell, J. Bacteriol, 1972, 110, 667) by Brij-lysis (D. B. Clewell et al, Proc. Natl. Acad. Sci., USA, 1969, 62, 1159) and subsequent caesium chloride-ethidium bromide density gradient centrifugation (A. Colman et al, Eur. J. Biochem, 1978, 91, 303). 55 A rapid, small scale plasmid isolation technique (Birnboim et al. Nucl. Acids Res. 1979, 7, 1513) was also employed for screening purposes. Chromosomal DNA from the donor *Pseudomonas* strain (RS-16) was prepared essentially as described by J. Marmar, J. Mol. Biol, 1961, 3, 208.

Restriction, ligation and transformation methods

Restriction endonucleases and DNA ligase were purchased from Bethesda Research Laboratories and used in the buffers and under the conditions recommended by the supplier. Transformation of *E. coli* was essentially as described by S. N. Cohen et al., Proc. Natl. Acad. Sci., USA, 1972, 69, 2110, while *Ps. putida* was transformed by the method of M. Bagdasar'ian and K. N. Timmis, Current Topics in Microbiology and 65 Immunology, Eds. P. H. Hofschneider and W. Goebel, Springer Verlag, Berlin, 1981, p. 47.

Agarose gel electrophoresis

Digests were electrophoresed in 0.8% agarose slab gels (10 cm × 20 cm × 0.5 cm) on a standard vertical system (Raven), employing Tris-borate-EDTA buffer. Electrophoresis of undigested DNA was at 125V, 50 mA for 3 hours, while digested DNA was electrophoresed at 15V, 10 mA for 16 hours. Fragment sizes were estimated by comparison with fragments of λ DNA digested with *Hind*III and λ DNA cut with both *Hind*III and *Eco*RI. Fragments were isolated from gels using electroelution (M. W. McDonnell et al, Proc. Natl. Acad. Sci, USA, 1977, 74, 4835).

Determination of carboxypeptidase G₂ activity

Bacteria were grown in 1 litre batch culture and 100 ml samples taken at various stages in the growth phase. Samples were cooled on ice, centrifuged at 13,000×g for 10 minutes and resuspended and frozen in 5 ml of 0.1 M Tris HCl, pH 7.3 containing 0.2 mM ZnSO₄. The cells were disrupted using a MSE Ultrasonic Disintegrator (150 W) at medium frequency, amplitude 2, for three 30-second intervals on ice. Cell debris was removed by centrifugation at 10,000×g for 5 minutes. CPG₂ activity was determined after J. L. McCullough et al, J. Biol. Chem, 1971, 246, 7207. A 1 ml reaction cuvette containing 0.9 ml of 0.1 M Tris-HCl, pH 7.3 plus 0.2 mM ZnSO₄ and 0.1 ml of 0.6 mM methotrexate was equilibrated at 37°C. Enzyme extract was added to the test cuvette and the decrease in absorbance at 320 nm measured using a Pye-Unicam SP1800 double-beam spectrophotometer. Enzyme activity per ml extract was calculated as Δ 320 nm absorbance/min divided by 8.3, which is equivalent to the hydrolysis of 1 μ mol of MTX/min at 37°C. Protein concentration was determined by the method of M. M. Bradford, Anal. Biochem., 1976, 72, 248.

Cell fractionation techniques

Bacterial cultures were grown in the low phosphate medium of H. C. Neu and L. A. Heppel, (J. Biol. Chem., 1964, 240, 3685), supplemented with 100 μ g/ml ampicillin, to an OD₄₅₀ = 1.0. 40 ml of culture was centrifuged at 5000 g for 10 min, washed in 5 ml of 10 mM Tris-HCl pH 7.0, and resuspended in 0.9 ml of 0.58 M sucrose, 0.2 mM DTT, 30 mM Tris-HCl pH 8.0. Conversion to spheroplasts was achieved by the addition of 20 μ l of lysozyme (2 mg/ml), 40 μ l 0.1 M EDTA, and incubation at 23° for 10 min (H. C. Neu et al, J. Biol. Chem., 1964, 239, 3893). The spheroplasts were placed on ice and 0.1 ml of 30% (w/v) BSA added, followed by 5 ml of sucrose-tris buffer. Sedimentation of the spheroplasts was achieved by centrifugation at 5000 g for 10 min and the supernatant retained as the 'periplasmic' fraction. The pellet was resuspended in 5 ml 10 mM Tris-HCl, 0.2 mM DTT pH 7.0 and sonicated at 20 Kc/sec, 2 Amps for 15 sec. Remaining whole cells were removed by centrifugation at 1000×g for 10 min. Centrifugation at 100000×g for 1 hr, at 4°C, separated the soluble (cytoplasmic) proteins from the particulate (membrane-bound) proteins. The membrane pellet was resuspended in 1 ml of 10 mM Tris-HCl, 0.2 mM DTT, pH 7.0.

CPG₂ was assayed as described. Alkaline phosphatase was assayed according to J. Miller, Experiments in Molecular genetics, Cold Spring Harbor Laboratory, Cold Spring Harbor, New York, 1972, NADH oxidase according to M. J. Osborn et al, J. Biol. Chem., 1972, 247, 3962 and glyceraldehyde-3-phosphate dehydrogenase after K. Suzuki et al, FEMS, 1971, 13, 217.

Example 1

Preparation of recombinant plasmid pNM1 (A plasmid containing both the present leader sequence polynucleotide and the CPG₂ structural gene).

To isolate the gene for carboxypeptidase G₂ together with the leader sequence polynucleotide chromosomal DNA prepared from the *Pseudomonas* host (strain RS-16) was partially digested with *Sau*3A and fragments of between 6—8 Md isolated from agarose gels by electroelution. The 'sized' DNA was ligated with alkaline phosphatase treated *Bam*HI cut pBR322, transformed into *E. coli* W5445, and Ap^r transformants selected. Of the 3,500 Ap^r colonies obtained, approximately 70% were Tc^s. Utilisation of a rapid plasmid isolation technique on 50 Ap^r Tc^s transformants demonstrated that 90% of the gene bank harboured plasmids of the expected size. As a further check on the authenticity of the gene bank, the individual clones were screened for the acquisition of a Leu⁻ phenotype. Two such clones were identified. Both carried a plasmid capable of transforming *leuB* (B-isopropylmalate dehydrogenase) *E. coli* mutants to prototrophy.

Acquisition of a functional CPG₂ gene should enable *E. coli* to utilise folic acid as a carbon source. The 2,400 gene bank clones were screened for the ability to grow on minimal medium containing folate as the sole source of carbon (i.e. Fol⁺). A single Fol⁺ clone was detected and shown to harbour a plasmid capable of transforming plasmid-minus W5445 to the Fol⁺ phenotype. Classical restriction mapping of this plasmid (pNM1) was undertaken which revealed the presence of a 5.9 Md insert of pseudomonad DNA within pBR322. The restriction enzyme cleavage site map of pNM1 is given in Figure 1. The nucleotide sequence of the leader sequence polynucleotide and the CPG₂ structural gene is given in Table 1.

Example 2

Subcloning of plasmid pNM1 to form pNM111

In order to pinpoint the position of the CPG₂ gene and the leader sequence polynucleotide within the 5.9 Md insert, subcloning of various restriction enzyme fragments, into pBR322, was undertaken. A functional CPG₂ gene was shown not to occur on *Xho*I or *Sph*I fragments of the pNM1 insert, but was

present on a 3.1 Md *Bgl*II fragment. This latter fragment was cloned into the *Bam*HI site of pBR322 to give pNM11 (6.0 Md). A further reduction in the size of pNM11 was achieved by digesting with *Sa*I and relegating the resultant fragment to yield pNM111. In addition, plasmids in which the smaller 0.95 Md *Sa*I fragment had become inserted in the opposite orientation to the parent plasmid (pNM11) were *Fol*⁻. Taken together these subcloning results indicate that the CPG₂ gene and the leader sequence polynucleotide lie between the *Bgl*II site at 4.14 and the *SA*I site at 6.03 on Pnml. Furthermore, the gene contains a *Sph*I (5.17), *Sa*I (5.07) and at least one *Xho*I (4.56 and/or 5.56) site. The restriction enzyme cleavage site map of pNM111 is given in Figure 2.

10 Example 3

Preparation of recombinant plasmid pNM14. (A plasmid containing both the present leader sequence polynucleotide and the CPG₂ structural gene)

The 3.1 Md *Bgl*II fragment from Example 2 above was partially digested with *Sau*3A. These fragments were then cloned into the *Bam*HI site of pAT153 and transformed into *E. coli* W5445. Of the two *Ap*^r *Tc*^r *Fol*⁺ colonies obtained, one contained a plasmid which had acquired an extra *Sa*I and *Bam*HI site, this was pNM14. The restriction enzyme cleavage site map of pNM14 is given in Figure 3. Sequencing of the leader sequence polynucleotide and the CPG₂ structural gene present in pNM14 gave the nucleotide structure shown in Table 1. DNA sequencing of pNM14 also revealed that the *Sa*I—*Bam*HI fragment was a duplication of a segment of DNA from within the insert (marked * on Figure 3) composed of two contiguous *Sau*3A fragments.

Example 4 and 5

Preparation of recombinant plasmids pNM21 and pNM22 (Plasmids containing both the present leader sequence polynucleotide and the CPG₂ structural gene)

The 3.1 Md *Bgl*II fragment from Example 2 was cloned into the *Bam*HI site of pAT 153 and transformed into *E. coli* W5445. Two *Ap*^r *Tc*^r *Fol*⁺ colonies were obtained, one containing a plasmid pNM21 in which the fragment was inserted in the opposite orientation to pNM1 and one containing a plasmid pNM22 in which the fragment was inserted in the same orientation as pNM1. The restriction enzyme cleavage site maps of pNM21 and pNM22 are given in Figures 4 and 5 respectively.

The two plasmids, pNM21 and pNM22 both transformed *E. coli* to *Fol*⁺, indicating that a pseudomonad promoter was present on the 3.1 Md fragment. However, cells carrying the plasmid pNM21, in which the *Bgl*II fragment was cloned in the opposite orientation to pNM1, exhibited more rapid growth with folic acid as the sole carbon source. This difference was clearly visible on agar medium, where colonies developed concentric yellow "halos" of precipitated pteric acid, the insoluble product of folate hydrolysis.

Confirmation that pNM21 gave enhanced expression of CPG₂ over pNM22, was obtained by assaying enzyme production during batch growth of cells containing either plasmid. (The cells were grown in complex medium supplemented with 1% (w/v) glucose and where appropriate 0.05% (w/v) folic acid. The generation time was 56—66 min. The culture was sampled at hourly intervals and whole cells were disrupted by sonication. Enzyme activity was determined in the centrifugal extract). Results are given in Table 2.

The expression of CPG₂ from the plasmids pNM22 and pNM1 was 2.5 units/litre of culture, representing 0.005% soluble protein. In contrast, expression from pNM21 was 3000—3500 units/litre of culture, which represented 4.7% soluble protein. As the cloned gene is inserted into the *Bam*HI site of pAT153, the observed higher expression of pNM21 is almost certainly due to transcriptional read through from the *Tc* promoter. The low expression of CPG₂ carried on plasmids pNM1 and pNM22 is consistent with the view that *Pseudomonas* promoters function poorly in *E. coli*. It is also apparent from Table 2 that in the presence of folate there is a two-fold increase in the specific activity of enzyme measured in cell sonicates. This phenomenon has been observed in all experiments, but does not seem to be associated with classical induction of the CPG₂ gene, as overall enzyme yield in the presence or absence of folate remains at about 3000 u/litre culture. It in fact reflects a consistent depression in the soluble protein levels measured in sonicates from cells grown in the presence of folate. There is no obvious difference in growth rate of cells grown with folate and the reasons for this result are not clear.

TABLE 2

Carboxypeptidase G production by *E. coli* W5445, containing the plasmids pNM1, pNM21 and pNM22

5	Culture	Carboxypeptidase G ₂ specific activity (U/MG soluble protein)

20	6	.005	.024	.014	.023	13.7	24.1
	7	.015	.029	.024	.043	13.2	20.6
25	8	.013	.028	.024	.046	13.0	23.6

Expression of the cloned gene in *Ps. putida*

The observation that the CPG₂ gene was expressed in *E. coli* regardless of the orientation of the gene within the vector suggested that the promoter region of the CPG₂ gene had been cloned with the structural gene and the leader sequence polynucleotide. The low expression of CPG₂ within *E. coli* from its natural promoter (pNM1, pNM22, pNM111) confirmed other findings that *Pseudomonas* promoters are poorly recognised by *E. coli* RNA polymerases. It would be expected that if the gene was introduced back into a pseudomonad cellular environment, then improved expression from the *Pseudomonas* promoter should result. The 3.1 Md *Bgl*III fragment was subcloned into the *Pseudomonas* cloning vector pKT230 at its single *Bam*HI site. Two plasmids were obtained, pNM31 and pNM32 representing the two possible orientations of the cloned gene. These plasmids were transformed into *Ps. putida* 2440 by the method of Bagdasarian and Timmis. *Pseudomonas* cells carrying both plasmids were cultured in minimal salts medium and enzyme production monitored.

Yields of 500–1000 units/litre of culture were obtained regardless of gene orientation within the plasmid. Specific activity of the enzyme in cell sonicates was 1.5 to 4.0 U/mg protein representing 0.3 to 0.7% soluble protein (compared with <0.05% soluble protein in the donor strain RS-16). This result strongly indicates that the CPG₂ promoter is present and operated in a pseudomonad background. When the same plasmids were transformed into *E. coli* W5445 12–40 Units/litre were found at specific activity <0.07 U/mg (<0.01% soluble protein).

Periplasmic localisation of CPG₂

There is evidence that CPG₂ is located in or near the periplasmic space of *Pseudomonas* strain RS-16. Pteric acid, the product of CPG₂ hydrolysis of folic acid is extremely insoluble and is found predominantly outside the cell in both liquid and solid media. Exogenous pteric acid is also seen in *E. coli* cultures containing the cloned gene when folic acid is present in the medium. This is clearly demonstrated by the "halo" of precipitated pteric acid observed around colonies carrying plasmids in which expression of CPG₂ is from the Tc promoter of pBR322 (e.g. pNM21).

The localisation of CPG₂ produced by *E. coli* cells carrying pNM21 was examined by the separation of cellular proteins into cytoplasmic, periplasmic, and whole membrane fractions. As a control, levels of three marker enzymes, alkaline phosphatase (periplasmic), glyceraldehyde-3-phosphate dehydrogenase (cytoplasmic) and NADH · O₂ oxidoreductase (membrane-bound), were also determined. As can be seen from Table 3 97% of the CPG₂ activity occurs in the periplasm, equivalent to the marker periplasmic enzyme, alkaline phosphatase. This confirms the presence in pNM21 of a leader sequence polynucleotide next to the CPG₂ gene that codes for a signal polypeptide according to this invention that promotes the secretion of CPG₂ from the cytoplasm into the periplasmic space.

Carboxypeptidase G₂ synthesised in *E. coli*

The specific activity of CPG₂ in crude cell extracts of cells carrying pNM21 was 50-fold higher than equivalent extracts from *Pseudomonas* strain RS-16. To determine whether the cloned gene = product in *E.*

coli had the same properties as CPG₂ from the pseudomonad, enzyme was purified from *E. coli* carrying pNM21. The specific activity of purified CPG₂ (single band SDS-PAGE) was 535 U/mg of protein, which compares to 550 U/mg of protein from the pseudomonad. CPG₂ purified from *E. coli* clone pNM21 co-chromatographed with CPG₂ from *Pseudomonas* strain RS-16 at a sub-unit molecular weight value of 42,000 daltons. Km values using methotrexate as substrate were 7.4×10^{-6} M and 8.0×10^{-6} M respectively. In addition, antiserum raised against the *Pseudomonas* enzyme indicated immunological identity between the *E. coli* and *Pseudomonas* CPG₂, as a confluent precipitation line was formed on Ouchterlony double diffusion analysis.

NADHOX=NADH · O₂ oxidoreductase

Example 6

Preparation of a recombinant plasmid containing both the present leader sequence polynucleotide and the β-Galactosidase structural gene

Plasmid pNM14 (Example 3) was treated with *Sau* 3A (GATC) and the fragments were cloned into the *Bam* HI site of M13 mp7 template DNA (single stranded DNA (Step A of Figure 6). The product carrying a 318bp *Sau* 3A fragment coding for the present signal polypeptide and the first 22 amino acids of CPG₂ (nucleotide sequence of this fragment shown in Table 4) was selected and made double stranded. The DNA coding for the signal polypeptide (and the first part of CPG₂) was then excised as an *Eco*RI fragment. This *Eco*RI fragment was then cloned into the promoter cloning vector *E. coli* pMC1403 (M. J. Casadaban *et al*, J. Bacteriol, 1980, 143, 971), which carries only the structural gene (*lac* Z) for β-galactosidase (i.e. no promoter and no ATG start codon) (Steps B and C of Figure 6). Plasmids were obtained in which the *Eco*RI fragment had inserted in both orientations, however, only those in which fusion of the CPG₂ sequence to the β-galactosidase sequence had occurred (i) yielded a 0.34 Kb fragment upon digestion with *Bam*HI; (ii) enabled the host cell to hydrolyse the colourless lactose analogue, BCIG, and impart a blue colouration to colonies. The 0.34 Kb *Bam*HI fragment has been recloned into M13mp7 and sequenced to confirm that fusion has occurred. The 'precursor' fusion produced will consist of the signal peptide, the first 22 amino acids of CPG₂, 6 amino acids derived from the M13mp7 and pMC1403 linker units, and β-galactosidase from its 8th amino acid onward.

Localisation experiments have been performed on cells carrying a plasmid coding for the 'fusion gene' where the cellular proteins have been fractionated into periplasmic, cytoplasmic and membrane fractions. In these experiments an organism (*E. coli* MC 1061) which is deleted for the *lac* Z gene was grown in phosphate medium (H. C. Neu *et al*, J. Biol. Chem., 1964, 240, 3685) and periplasmic enzymes were released from the harvested cells by conversion to spheroplasts. Separation of soluble proteins (cytoplasmic) from particulate proteins (membrane band) was achieved by sonicating the harvested spheroplasts and subsequent centrifugation at 100,000 g for 1 hr, to sediment the cell membrane (T. J. Silhary *et al*, Proc. Natl. Acad. Sci. USA, 1976, 73, 3423).

The results given in Table 5 demonstrate the presence of 50% of the β-galactosidase activity in the periplasmic space. This result is in direct contrast to similar work involving fusion of other periplasmic protein signal sequences to β-galactosidase, where the fusion proteins are not exported, but become jammed in the membrane (P. J. Bassford *et al*, J. Bacteriol, 1979, 139, 19 and S. D. Emr *et al*, J. Cell. Biol., 1980, 86, 701).

Example 7

Preparation of a recombinant plasmid, containing both the present leader sequence polynucleotide and the CPG₂ structural gene, able to replicate in *E. coli* and *S. cerevisiae*

A 2.03 kilobase *Bam*HI fragment coding for the present signal polypeptide and the entire CPG₂ molecule was cloned in both orientations into the *Bam*HI site of an *E. coli*/*S. cerevisiae* shuttle vector pROG5 (R. F. Sherwood and R. K. Gibson, The Molecular Biology of Yeast, 1979, Cold Spring Harbor Publications) to give plasmids pLEC3 and pLEC4 (Figure 7). These plasmids were transformed into *S. cerevisiae* strain LL20 by the lithium acetate induced transformation method described by Ito *et al.*, J. Bact., 1983, 153, 163. Yields equivalent to 10–20 units/litre of culture volume were obtained regardless of gene

orientation within the plasmid. Specific activity of the enzyme in total cell extracts was 0.2—0.3 u/mg protein representing 0.005% soluble protein. This level of expression from the pseudomonad promoter in a yeast background is similar to the level found when the gene was reading from its own promoter in *E. coli* (0.01% soluble protein).

- 5 Localisation experiments have been performed on yeast cells carrying the above plasmids by sphaeroplasting the cells using standard techniques described by J. B. D. Beggs, *Nature*, 1978, 275, 105. Periplasmic enzymes, localised outside of the cell membrane, were released when the cell wall was removed. The osmotic stabiliser (1.2M sorbitol) was then replaced by 0.1M Tris-HCl buffer, pH 7.3 containing 0.2 mM ZnCl₂ to lyse the sphaeroplasts and the whole centrifuged at 100,000×g for 1 hour to
10 separate proteins in the soluble cytoplasmic fraction from membrane bound proteins. The results in Table 6 demonstrate the presence of 64% of the CPG₂ activity in the periplasmic fraction and a further 16% associated with the cell membrane fraction.

8. A recombinant DNA transfer vector according to any preceding claim characterised in that the transfer vector is a plasmid.

45 9. A microorganism transformed by a transfer vector characterised in that the transfer vector is a recombinant DNA transfer vector according to any one of the preceding claims 1 to 8.

10. A microorganism according to claim 9 which is a bacterium of the species *E. coli* or *Pseudomonas* or a yeast of the species *Saccharomyces cerevisiae*.

11. A process for the preparation of a gene product characterised by
50 (a) culturing a microorganism according to either claim 9 or claim 10 in a culture medium to produce the gene product in the culture medium or the periplasmic space of the microorganism, and
(b) isolating the gene product from the culture medium or the periplasmic space of the microorganism.

12. A process according to claim 11 characterised in that the gene product is *Pseudomonas* carboxypeptidase G₂.

55 13. A process according to claim 11 characterised in that the gene product is a protein or polypeptide other than *Pseudomonas* carboxypeptidase G₂.

14. A process according to claim 13 characterised in that the gene product is a prokaryotic protein other than *Pseudomonas* carboxypeptidase G₂.

15. A process according to claim 14 characterised in that the gene product is *E. coli* β -galactosidase.

4. Rekombinanter DNA-Transfervektor nach Anspruch 1 oder 2, dadurch gekennzeichnet, daß das Strukturgen für ein anderes Protein oder Polypeptid codiert als Pseudomonas-Carboxypeptidase G₂.

5. Rekombinanter DNA-Transfervektor nach Anspruch 4, dadurch gekennzeichnet, daß das Strukturgen für ein anderes prokaryotisches Protein als Pseudomonas-Carboxypeptidase G₂ codiert.

20 6. Rekombinanter DNA-Transfervektor nach Anspruch 5, dadurch gekennzeichnet, daß das Strukturgen für β-Galactosidase aus E. coli codiert.

7. Rekombinanter DNA-Transfervektor nach Anspruch 3, enthaltend ein Polynukleotid der Formel

8. Rekombinanter DNA-Transfektor nach einem der vorstehenden Ansprüche, dadurch gekennzeichnet, daß der Transfektor ein Plasmid ist.
9. Durch einen Transfektor transformierter Mikroorganismus, dadurch gekennzeichnet, daß der Transfektor ein rekombinanter DNA-Transfektor nach einem der Ansprüche 1 bis 8 ist.
10. Mikroorganismus nach Anspruch 9, der ein Bakterium der Gattung *E. coli* oder *Pseudomonas* oder eine Hefe der Gattung *Saccharomyces cerevisiae* ist.
11. Verfahren zur Herstellung eines Genprodukts, gekennzeichnet durch
 - (a) Züchten eines Mikroorganismus nach Anspruch 9 oder 10 in einem Kulturmedium zur Herstellung des Genprodukts in Kulturmedium oder im periplasmatischen Raum des Mikroorganismus, und
 - (b) Isolieren des Genprodukts aus dem Kulturmedium oder dem periplasmatischen Raum des Mikroorganismus.
12. Verfahren nach Anspruch 11, gekennzeichnet durch Herstellung von *Pseudomonas*-Carboxypeptidase G₂ als Genprodukt.
13. Verfahren nach Anspruch 11, gekennzeichnet durch Herstellung eines anderen Proteins oder Polypeptids als *Pseudomonas*-Carboxypeptidase G₂ als Genprodukt.
14. Verfahren nach Anspruch 13, gekennzeichnet durch eines anderen prokaryotischen Proteins als *Pseudomonas*-Carboxypeptidase G₂ als Genprodukt.
15. Verfahren nach Anspruch 14, gekennzeichnet durch β -Galactosidase aus *E. coli* als Genprodukt.

35 Revendications

1. Un vecteur de transfert d'ADN recombinant comprenant une séquence guide de polynucléotide en aval et en phase de lecture relativement à un promoteur de bactérie ou de levure et à un site de liaison ribosomique procaryotique et en amont et en phase de lecture relativement à un gène de structure, caractérisé en ce que la séquence guide de polynucléotide code pour un polypeptide signal de formule I

Met-Arg-Pro-Ser-Ile-His-Arg-Thr-Ala-Ile-Ala
Ala-Val-Leu-Ala-Thr-Ala-Phe-Val-Ala-Gly-Thr.

2. Un vecteur de transfert d'ADN recombinant selon la revendication 1, caractérisé en ce que la séquence guide de polynucléotide répond à la formule II

5'—	ATG	CGC	CCA	TCC	ATC	CAC	CGC	ACA	
	GCC	ATC	GCC	GCC	GTG	CTG	GCC	ACC	II
	GCC	TTC	GTG	GCG	GGC	ACC	—3'		

3. Un vecteur de transfert d'ADN recombinant selon l'une ou l'autre des revendications 1 ou 2, caractérisé en ce que le gène de structure code pour la carboxypeptidase G₂ de *Pseudomonas* (CPG₂).
4. Un vecteur de transfert d'ADN recombinant selon l'une ou l'autre des revendications 1 ou 2, caractérisé en ce que le gène de structure code pour une protéine ou un polypeptide autre que la carboxypeptidase G₂ de *Pseudomonas*.
5. Un vecteur de transfert d'ADN recombinant selon la revendication 4 caractérisé en ce que le gène de structure code pour une protéine procaryotique autre que la carboxypeptidase G₂ de *Pseudomonas*.
6. Un vecteur de transfert d'ADN recombinant selon la revendication 5 caractérisé en ce que le gène de structure code pour la β -galactosidase de *E. coli*.
7. Un vecteur de transfert d'ADN recombinant selon la revendication 3 comprenant un polynucléotide de formule

8. Un vecteur de transfert d'ADN recombinant selon l'une quelconque des revendications précédentes caractérisé en ce que le vecteur de transfert est un plasmide.

9. Un micro-organisme transformé par un vecteur de transfert caractérisé en ce que le vecteur de transfert est un vecteur de transfert d'ADN recombinant selon l'une quelconque des revendications précédentes 1 à 8.

10. Un micro-organisme selon la revendication 9 qui est une bactérie de l'espèce *E. coli* ou *Pseudomonas* ou une levure de l'espèce *Saccharomyces cerevisiae*.

11. Un procédé pour la préparation d'un produit génique caractérisé par

(a) la culture d'un micro-organisme selon soit la revendication 9 soit la revendication 10 dans un milieu de culture pour produire le produit génique dans le milieu de culture ou dans l'espace périplasmique du micro-organisme et

(b) l'isolement du produit génique du milieu de culture ou de l'espace périplasmique du micro-organisme.

12. Un procédé selon la revendication 11 caractérisé en ce que le produit génique est la carboxypeptidase G₂ de Pseudomonas.

5 13. Un procédé selon la revendication 11 caractérisé en ce que le produit génique est une protéine ou un polypeptide autre que la carboxypeptidase G₂ de Pseudomonas.

14. Un procédé selon la revendication 13 caractérisé en ce que le produit génique est une protéine procaryotique autre que la carboxypeptidase G₂ de Pseudomonas.

10 15. Un procédé selon la revendication 14 caractérisé en ce que le produit génique est la β -galactosidase de E. coli.
